

# Overview

Computer Security – Principles and Practice (Pearson, fourth edition)  
W. Stallings, L. Brown

\* These slides are an adaptation of the original slides of the authors of the book

# Learning objectives

Describe the key security requirements

Discuss the types of threats and attacks

Summarize the functional requirements for computer security

Explain the fundamental security design principles

...

# Before security...

---

ASK  
YOURSELF:

What assets do you need to protect?  
How those assets are threatened?  
How can you counter those threats?

Pictures! Bank account  
but it is protected by  
the bank. Some elements  
are our responsibility to  
keep.

# Computer security concepts

---

The NIST Internal/Interagency Report NISTIR 7298 (*Glossary of Key Information Security Terms*, May 2013) defines the term **computer security** as follows: (responsible for defining standards)

- ① Measures and controls that ensure **confidentiality, integrity, and availability** of information system **assets** including hardware, software, firmware, and information being processed, stored, and communicated.

1. Defining what assets can be regarding computer security.
2. We introduce the 3 requirements of computer security.

# Key Security Concepts (CIA)

↳ Disclosure of information can happen in many ways. What's more, sometimes information must be made available to only a specific person at specific times

## Confidentiality

- Preserving authorized restrictions on information access and disclosure, including means for protecting personal privacy and proprietary information

## Integrity

- Guarding against improper information modification or destruction, including ensuring information nonrepudiation and authenticity

↳ Info must not be altered. But it's not related to data only. Concerns the hardware and software. A virus that changes the PC behaviour is a threat to integrity.

## Availability

- Ensuring timely and reliable access to and use of information  
↳ I should have guaranteed access to my assets.

Nonrepudiation = preventing someone to deny their action

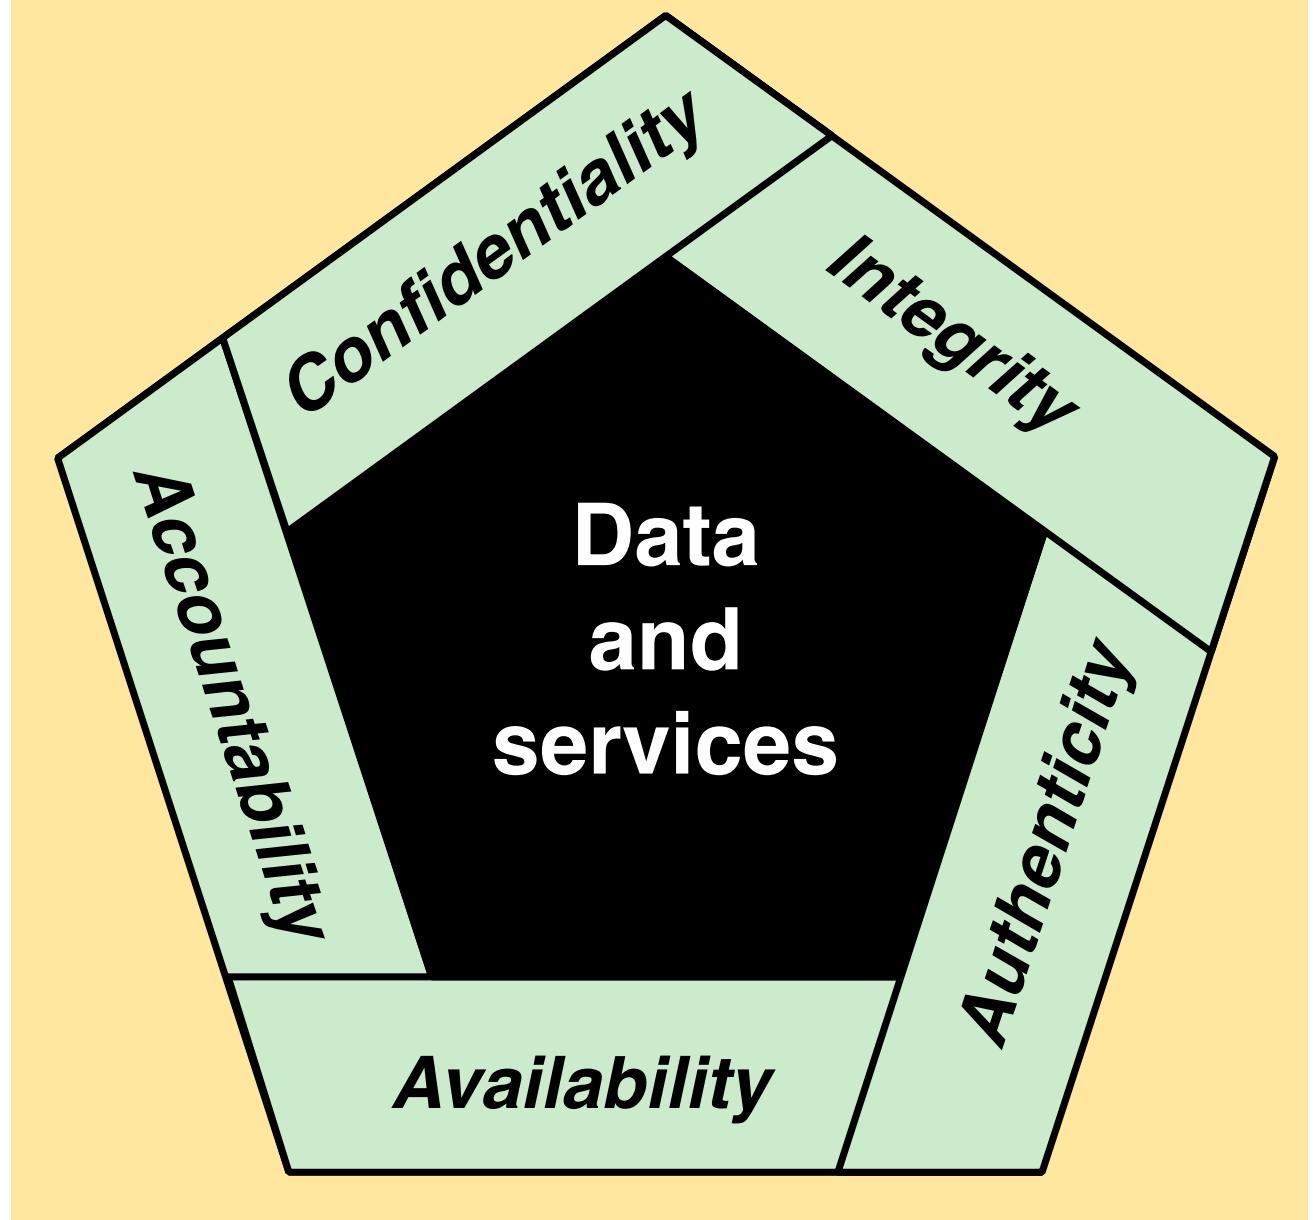

Authenticity = genuinity

# The CIA Triad

- Confidentiality:
  - Data confidentiality : Assures that private or confidential information is not made available or disclosed to unauthorized individuals.
  - Privacy : Assures that individuals control how their information is stored, accessed and shared
- Integrity:
  - Data integrity : Assures that information and programs are changed only in a specified and authorized manner.
  - System integrity : Assures that a system performs its intended function in an unimpaired manner
- Availability:
  - Ensuring timely and reliable access to and use of information.

# Essential network and security requirements

---

CIA implicitly include those two, but some sources find it interesting to separate those two.

## Authenticity & Accountability

This one is more directed towards us because it calls for a specific action.

Cameras can offer accountability but may not be sufficient. If you have a robust accountability system

that may convince malicious actors to choose another system. → It also helps you to understand what happens in case of an attack.

- **Authenticity:** The property of being genuine and being able to be verified and trusted
  - Regards the validity of a transmission, a message, or message originator.
  - This means verifying that users are who they say they are and that each input arriving at the system came from a trusted source.
- **Accountability:** ability to uniquely trace the actions of an entity
  - This supports nonrepudiation, deterrence, fault isolation, intrusion detection and prevention, and after-action recovery and legal action

track all the actions applied to a given asset

# Levels of Impact

Classifying the impact of an attack is difficult but important.

Asset Value assessment is important so you know the level of protection you have to implement.  
↳ So you have to classify the level of impact.

## Low

## Moderate

## High

Ability for an organization to stay active, but also regarding physical tanks and so on.

The loss could be expected to have a limited adverse effect on organizational operations, organizational assets, or individuals

The loss could be expected to have a serious adverse effect on organizational operations, organizational assets, or individuals

The loss could be expected to have a severe or catastrophic adverse effect on organizational operations, organizational assets, or individuals

# Question for you

---

*It depends on the person or organization!*

GIVE EXAMPLES OF ASSETS  
OF LOW, MODERATE AND  
HIGH IMPACT FOR EACH  
SECURITY CONCEPT

I MEAN: CONFIDENTIALITY,  
INTEGRITY AND  
AVAILABILITY

# Computer Security Challenges (I)

Security mechanisms typically based on some secret info: raises questions about ... which may introduce vulnerabilities.

add elements to a system to make it more secure but don't so you can introduce errors and bugs

Changing the procedures can be counterintuitive or not accepted by user, introducing weaknesses

it's not always that easy

1. Computer security is not as simple as it might first appear to the novice
2. In developing a particular security mechanism or algorithm, one must always consider potential attacks on those security features
3. Procedures used to provide particular services are often counterintuitive
4. Physical and logical placement of security mechanisms needs to be determined
5. Security mechanisms typically involve several algorithms or protocols and require that participants be in possession of some secret information which raises questions about the creation, distribution, and protection of that secret information

# Computer Security Challenges (II)

perceived as  
overhead.

6. Attackers only need to find a single weakness, while the designer must find and eliminate all weaknesses to achieve perfect security
7. Security is still too often an afterthought to be incorporated into a system after the design is complete, rather than being an integral part of the design process
8. Security requires regular and constant monitoring
9. There is a natural tendency on the part of users and system managers to perceive little benefit from security investment until a security failure occurs
10. Many users and even security administrators view strong security as an impediment to efficient and user-friendly operation of an information system or use of information

Assets: hardware, software, data, communication facilities, physical infrastructures and personnel.

# Computer Security Terminology

(RFC 2828, Internet Security Glossary, May 2000)

**System Resource (Asset):** A major application, general support system, high impact program, physical plant, mission critical system, personnel, equipment, or a logically related group of systems.

**Adversary (threat agent):** individual, group, organization, or government that conducts or has the intent to conduct detrimental activities.

**Threat:** Any circumstance or event with the potential to adversely impact:

- organizational operations (including mission, functions, image, or reputation)
- organizational assets,
- individuals,
- other organizations,
- or even an entire Nation

through an information system via unauthorized access, destruction, disclosure, modification of information, and/or denial of service.

**Attack:** Any kind of malicious activity that attempts to collect, disrupt, deny, degrade, or destroy information system resources or the information itself.

cause harm or do something not permitted by the security policy  
ISV has a more or less explicit impact.

# Computer Security Terminology

(RFC 2828, Internet Security Glossary, May 2000)

define all in terms of rules, practices what tells how security should be managed and which entity can do what.

Risk: A measure of the extent to which an entity is threatened by a potential circumstance or event, and typically a function of:

1. the adverse impacts that would arise if the circumstance or event occurs;
2. the likelihood of occurrence.

Vulnerability: Weakness in an information system, system security procedures, internal controls, or implementation that could be exploited or triggered by a threat source.

Security Policy: A set of criteria for the provision of security services. It defines and constrains the activities of a data processing facility in order to maintain a condition of security for systems and data.

Countermeasure: A device or techniques that has as its objective:

- the impairment of the operational effectiveness of undesirable or adversarial activity, (or reduce the effect of an attack)
- or the prevention of espionage, sabotage, theft, or unauthorized access to or use of sensitive information or information systems. (also enable com. increase prevention)

Reduce risk: reduce impact in case an attack occurs or reduce probability of an attack.  
↳ requires assessing the impact of an attack!

# Security policy

---

- Several factors to be considered in the development of a security policy:
  - The value of the assets being protected
  - The vulnerabilities of the system *and. The impact of threats on assets.*
  - Potential threats and the likelihood of attacks
- Relevant tradeoffs: *you do not want to pay for overkill*
  - Ease of use versus security
  - Cost of security versus cost of failure and recovery
- The security policy is a business decision, possibly influenced by legal requirements.  
*↓ implementation vs technical.*

# Computer Security Terminology

---

(RFC 2828, Internet Security  
Glossary, May 2000)

**Adversary (threat agent):** individual, group, organization, or government that conducts or has the intent to conduct detrimental activities.

**Attack:** Any kind of malicious activity that attempts to collect, disrupt, deny, degrade, or destroy information system resources or the information itself.

**Countermeasure:** A device or techniques that has as its objective the impairment of the operational effectiveness of undesirable or adversarial activity, or the prevention of espionage, sabotage, theft, or unauthorized access to or use of sensitive information or information systems.

**Risk:** A measure of the extent to which an entity is threatened by a potential circumstance or event, and typically a function of 1) the adverse impacts that would arise if the circumstance or event occurs; and 2) the likelihood of occurrence.

# Computer Security Terminology

---

(RFC 2828, Internet Security  
Glossary, May 2000)

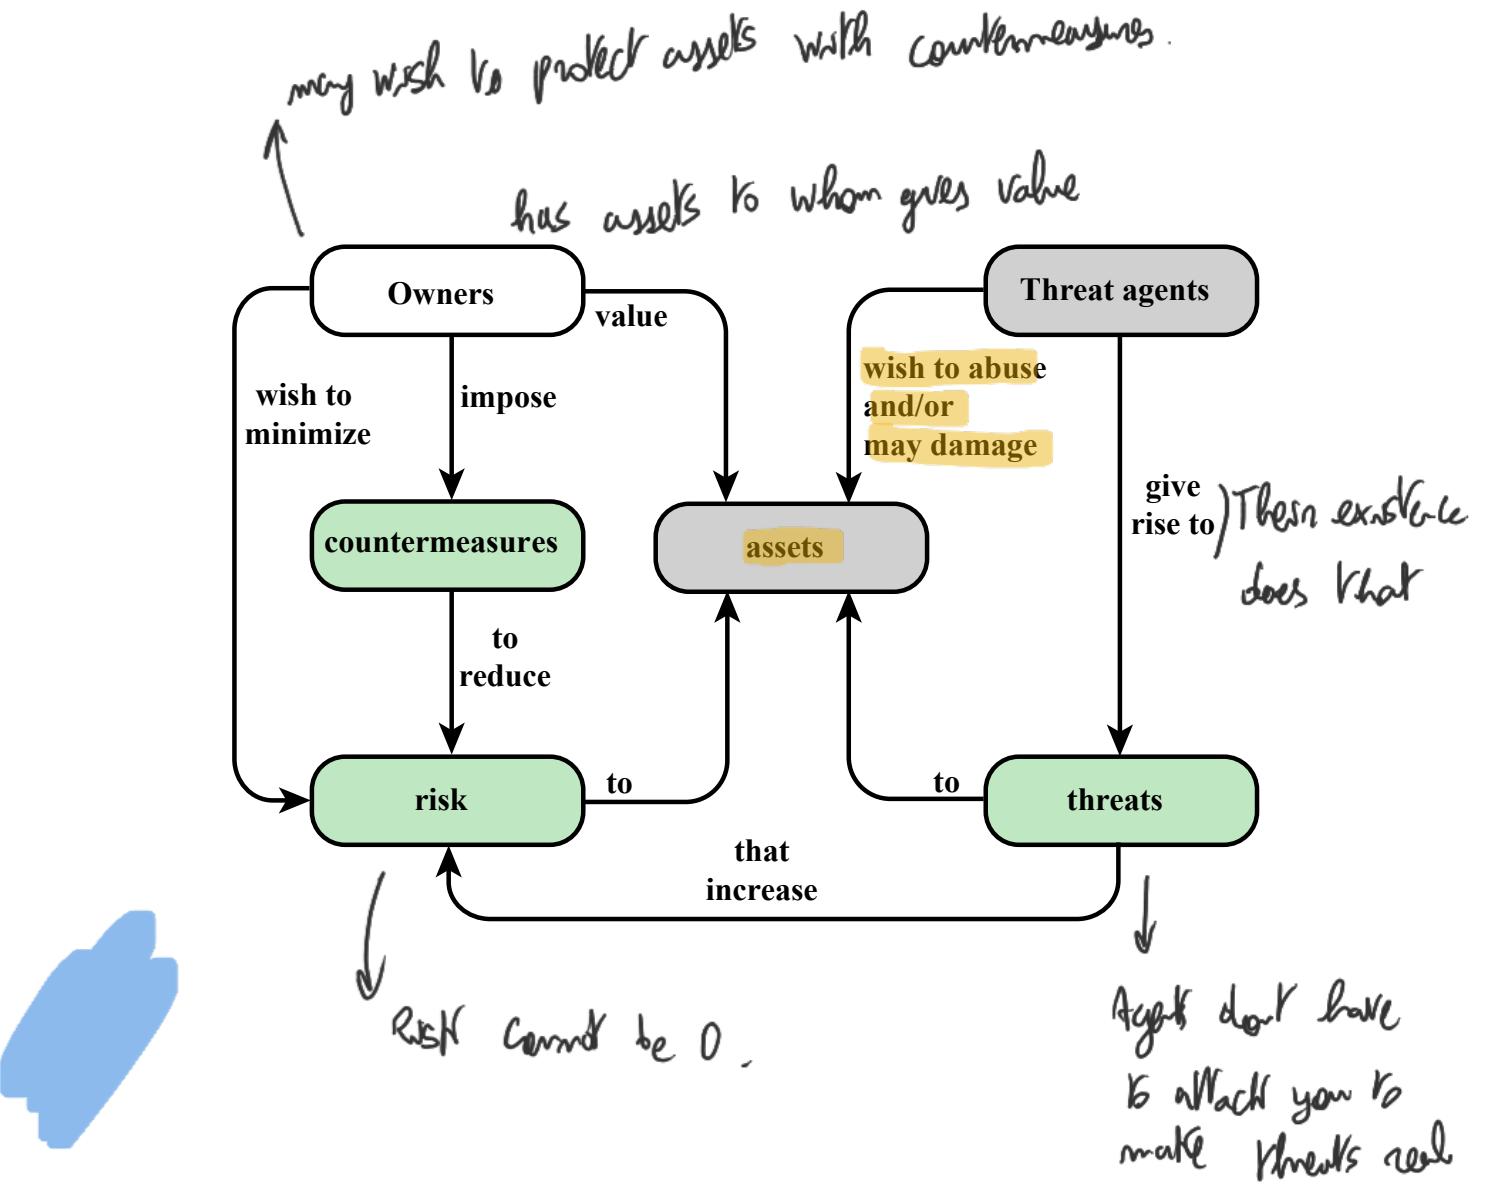

**Security Policy:** A set of criteria for the provision of security services. It defines and constrains the activities of a data processing facility in order to maintain a condition of security for systems and data.

**System Resource (Asset):** A major application, general support system, high impact program, physical plant, mission critical system, personnel, equipment, or a logically related group of systems.

**Threat:** Any circumstance or event with the potential to adversely impact organizational operations (including mission, functions, image, or reputation), organizational assets, individuals, other organizations, or the Nation through an information system via unauthorized access, destruction, disclosure, modification of information, and/or denial of service.

**Vulnerability:** Weakness in an information system, system security procedures, internal controls, or implementation that could be exploited or triggered by a threat source.

# Security concepts and relationships

# Assets of a Computer System

Hardware

Software

Data

Communication facilities and networks

# Vulnerabilities, Threats and Attacks

Ex; overhear sensitive information

Requires no damage anything to the system. Passive attack is not directly detected.

Categories of vulnerabilities: the system may become...

- Corrupted (loss of integrity)
- Leaky (loss of confidentiality)
- Unavailable or very slow (loss of availability)

Threats

- Capable of exploiting vulnerabilities
- Represent potential security harm to an asset

ALREADY DISCUSSED

Attacks (threats carried out) classification

- Passive – attempt to learn or make use of information from the system that does not affect system resources
- Active – attempt to alter system resources or affect their operation
- Insider – initiated by an entity inside the security perimeter
- Outsider – initiated from outside the perimeter

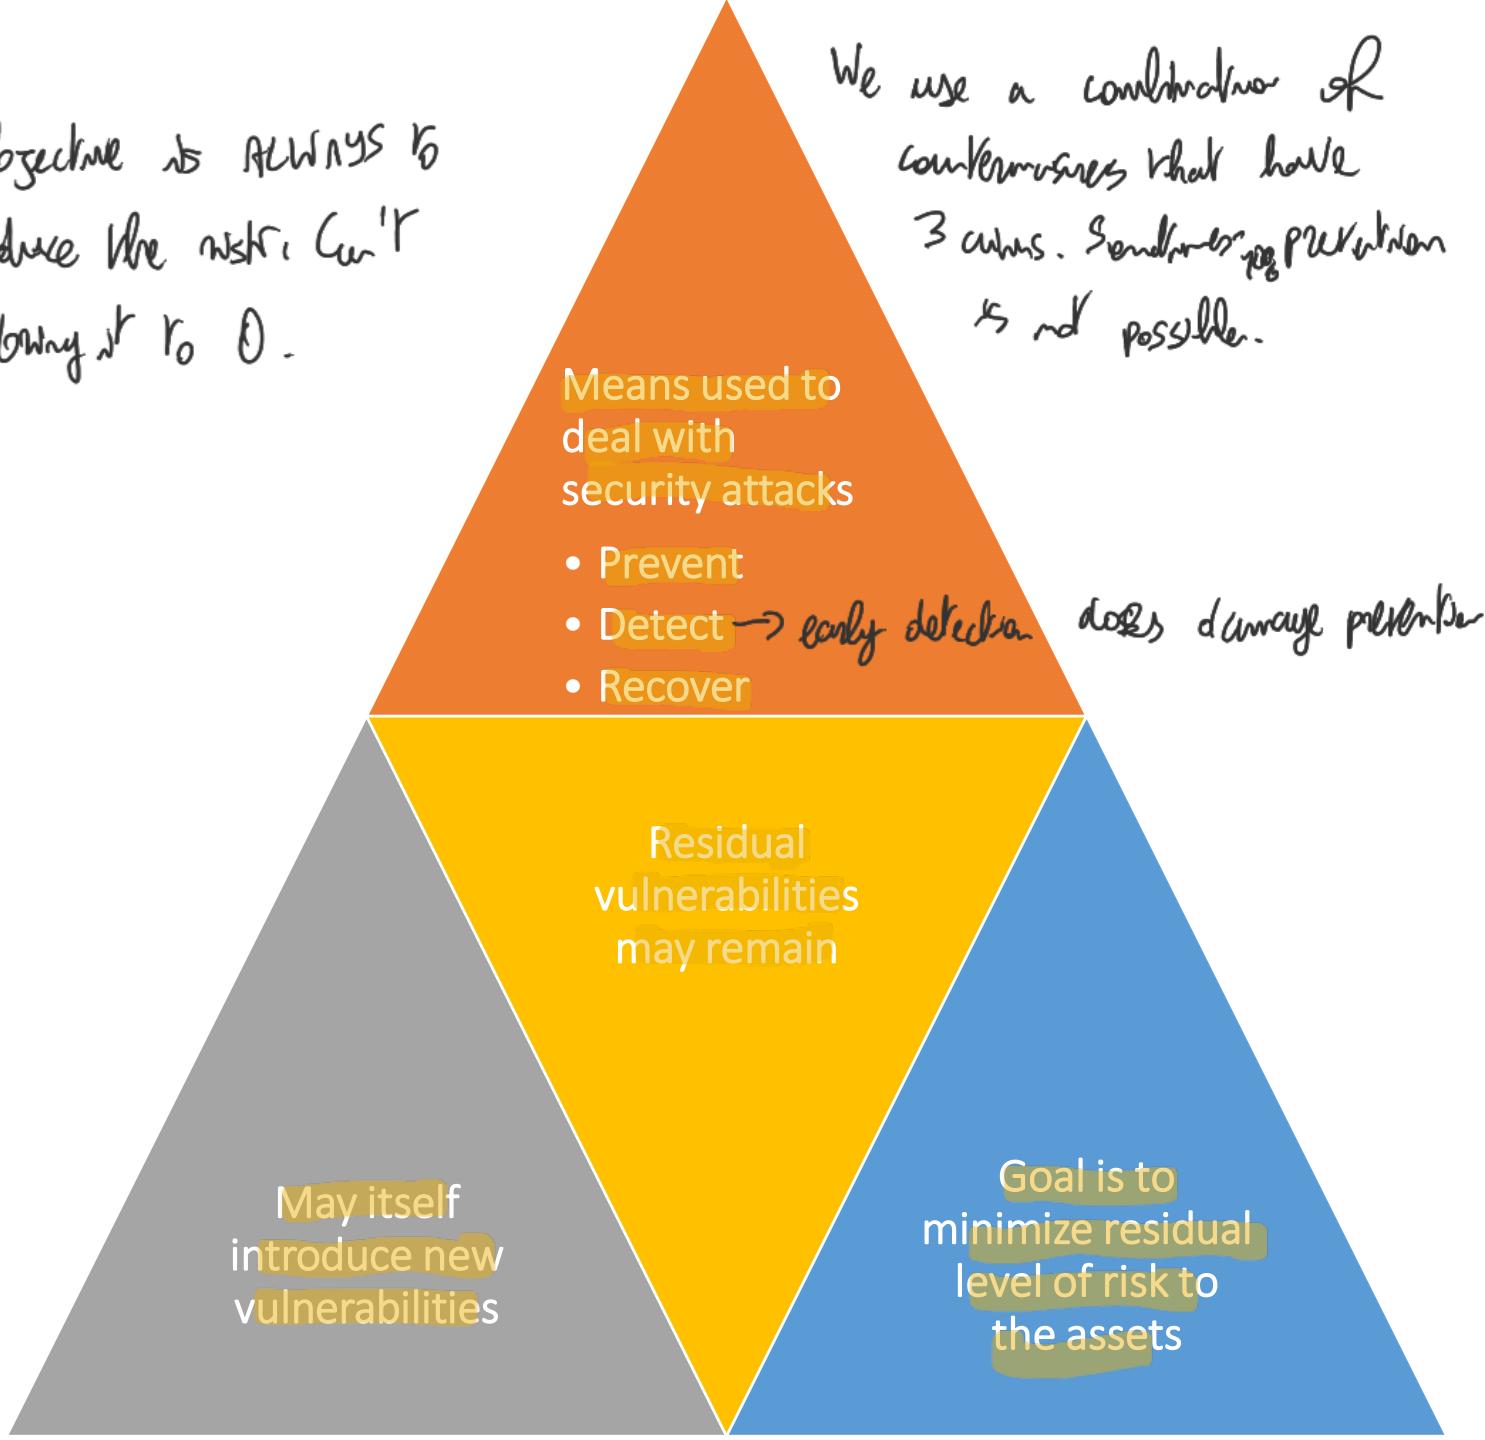

Attack to detect

# Counter-measures

---

Objective is ALWAYS to reduce the risk. Can't bring it to 0.

We use a combination of countermeasures that have 3 arms. Sometimes prevention is not possible.

# Questions & problems

---

CONSIDER AN ORGANIZATION MANAGING PUBLIC INFORMATION ON ITS  
WEB SERVER.

ASSIGN A LOW, MODERATE, OR HIGH IMPACT LEVEL FOR THE LOSS OF  
CONFIDENTIALITY, AVAILABILITY, AND INTEGRITY, RESPECTIVELY.

JUSTIFY YOUR ANSWER.

# Threats, attacks and assets

---

# Threat Consequences

↳ categories: a threat may address different categories.

The four kinds of threat consequences (based on RFC 4949):

- **Unauthorized disclosure:**
  - It is a threat to confidentiality
  - occurs when an unauthorized entity gains access to data
- **Deception:**
  - It is a threat to either system integrity or data integrity
  - Occurs when an authorized entity receives false data and believe it is true
- **Disruption:**
  - It is a threat to availability or system integrity
  - Occurs when the correct system functionality is interrupted or prevented
    - ↳ you can destroy a system  
so compromise the integrity
    - ↳ System does not work as it should or at all
- **Usurpation:** Trojan horse
  - It is a threat to system integrity
  - Occurs when an unauthorized entity gains control of system services or functions

# Attacks resulting in unauthorized disclosure

\* In some situations you have confidential data and public data. The user might reason on public data to try to get to confidential

## Exposure:

↑ Conf. data that becomes available

- Sensitive data are directly released to an unauthorized entity.

## Interception:

- An unauthorized entity directly accesses sensitive data traveling between authorized sources and destinations.

## Inference:

- An unauthorized entity indirectly accesses sensitive data (but not necessarily the data contained in the communication) by reasoning from characteristics or by-products of communications.

## Intrusion:

- An unauthorized entity gains access to sensitive data by circumventing a system's security protections.

# Attacks resulting in Deception

## Masquerade:

- An unauthorized entity gains access to a system or
- performs a malicious act by posing as an authorized entity.

↑ steal credentials and use them

## Falsification:

- False data deceive an authorized entity.

## Repudiation:

- An entity deceives another by falsely denying responsibility for an act.

# Attacks resulting in **Disruption**

## **Incapacitation:**

- Prevents or interrupts system operation by **disabling a system component.**

## **Corruption:**

- **Undesirably alters system operation** by adversely modifying system functions or data.

## **Obstruction:**

- A **threat action that interrupts delivery of system services** by hindering system operation.

# Attacks resulting in Usurpation

## **Misappropriation:**

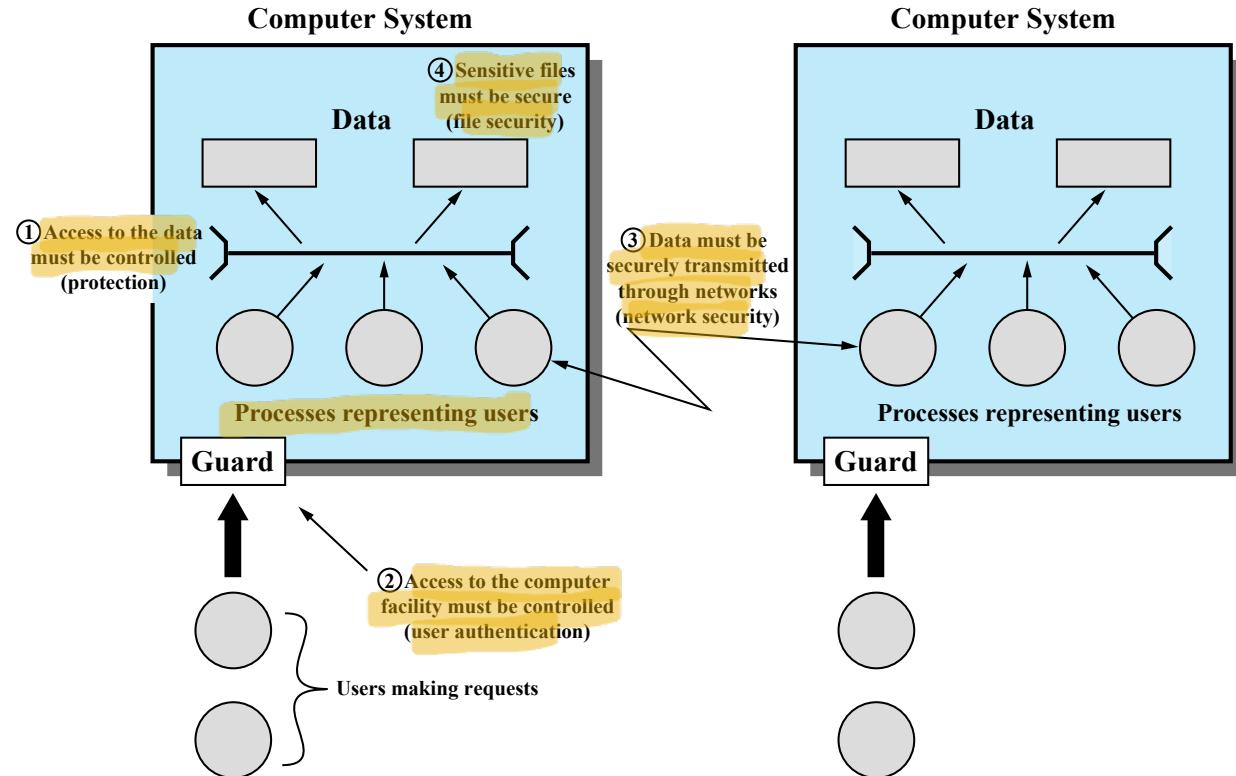

- An entity assumes unauthorized logical or physical control of a system resource.

## **Misuse:** *The actor makes the system behave in a way it shouldn't*

- Causes a system component to perform a function or service that is detrimental to system security.

# Scope of computer security

This figure depicts security concerns other than physical security, including controlling of access to computers systems, safeguarding of data transmitted over communications systems, and safeguarding of stored data

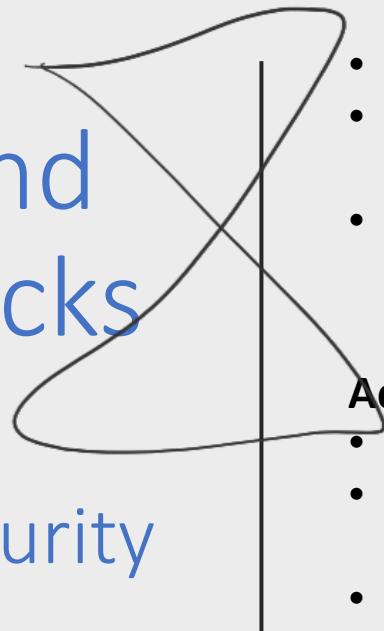

A computer system provides access to users. We should guard them. Processes access data and represent the user.

# Computer and network assets and threats

	Availability	Confidentiality	Integrity
Hardware	Equipment is stolen or disabled, thus denying service.	An unencrypted USB drive is stolen.	Make the HW operate out of its capabilities; destroying batteries...
Software	Programs are deleted, denying access to users.	An unauthorized copy of software is made.	A working program is modified, either to cause it to fail during execution or to cause it to do some unintended task.
Data	Files are encrypted or deleted, denying access to users.	An unauthorized read of data is performed. An analysis of statistical data reveals underlying data.	Existing files are modified, or new files are fabricated.
Communication lines and networks	Messages are destroyed or deleted. Communication lines or networks are rendered unavailable.	Messages are read. The traffic pattern of messages is observed.	Messages are modified, delayed, reordered, or duplicated. False messages are fabricated.

# Passive and active attacks in network security

---

## Passive attacks:

- Attempts to learn or make use of information from the system but does not affect system resources
- Eavesdropping on, or monitoring of, transmissions
- Goal of attacker is to obtain information that is being transmitted
- Two types:
  - Release of message contents
  - Traffic analysis

## Active attacks:

- Attempts to alter system resources or affect their operation
- Involve some modification of the data stream or the creation of a false stream
- Four categories:
  - Replay
  - Masquerade
  - Modification of messages
  - Denial of service

# Review question

---

Masquerade implemented  
↗

HOW WOULD YOU CLASSIFY THE FOLLOWING ATTACK?

UPON STEALING A BANK CUSTOMER'S COMMERCIAL IDENTITY (E.G., THEIR CREDIT CARD OR ACCOUNT INFORMATION), THE ATTACKER PRESENTS THOSE CREDENTIALS FOR THE MALICIOUS PURPOSE OF USING THE CUSTOMER'S CREDIT LINE TO STEAL MONEY

# Functional requirements

---

# Classification of countermeasures

- Several classifications of countermeasures aimed at reducing vulnerabilities and dealing with threats
- Classification according to functional requirements:
  - defined in FIPS 200 (*Minimum Security Requirements for Federal Information and Information Systems*).
- This standard enumerates 17 security-related areas:
  - They encompass a wide range of countermeasures to security vulnerabilities and threats.
  - Roughly, they can be divided into two categories:
    - Those that involve technical measures
    - Those that involve management issues

# Classification of countermeasures

Each functional area may involve both technical and management measures:

- **Technical measures:** access control, identification and authentication, system and communication protection, and system and information integrity.
- **Management measures:** awareness and training; audit and accountability; certification, accreditation, and security assessments; contingency planning; maintenance; physical and environmental protection; planning; personnel security; risk assessment; systems and services acquisition.
- Functional areas that overlap technical and management measures include configuration management, incident response, and media protection. HYBRID MEASURES

Tech alone is not sufficient. You have to consider management.

# Counter-measures (I)

- **Access Control:**
  - Limit information system access to authorized users and of processes that act on their behalf
  - limit the types of transactions and functions that authorized users are permitted to exercise.
- **Awareness and Training:**
  - Address managers and users of organizational information systems
  - Make them aware of the security risks and of the applicable laws, regulations, and policies;
  - Train all the personnel to carry out their duties according to the security protocols
- **Audit and Accountability:**
  - Create, protect, and retain information system audit records
  - to enable the monitoring, analysis, investigation, and reporting of unlawful, unauthorized, or inappropriate information system activity
  - Ensure that the actions of individual users can be uniquely traced so they can be held accountable for their actions.

# Counter-measures (II)

- **Certification, Accreditation, and Security Assessments:**
  - Periodically assess the security controls to determine their effectiveness
  - Develop and implement plans of action designed to correct deficiencies and reduce or eliminate vulnerabilities
  - Monitor information system security controls on an ongoing basis to ensure the continued effectiveness of the controls.
- **Configuration Management:**
  - Establish and maintain baseline configurations and inventories of organizational information systems (HW, SW, docs,...) throughout the respective system development life cycles
  - Establish and enforce security configuration settings for information technology products employed.
- **Contingency Planning:**
  - Establish, maintain, and implement plans for emergency response, backup operations, and post-disaster recovery
  - Ensure the availability of critical information resources and continuity of operations in emergency situations.

# Counter-measures (III)

- **Identification and Authentication:**
  - Identify system users, processes acting on behalf of users, or devices
  - Authenticate (or verify) the identities of those users, processes, or devices, as a prerequisite to allowing access.
- **Incident Response:**
  - Establish an operational incident-handling capability (includes preparation, detection, analysis, containment, recovery, and user-response activities)
  - Track, document, and report incidents to appropriate organizational officials and/or authorities.
- **Maintenance:**
  - Perform periodic and timely maintenance on organizational information systems
  - Provide effective controls on the tools, techniques, mechanisms, and personnel used to conduct information system maintenance.

# Counter-measures (IV)

- **Media Protection:**
  - Protect information system media, both paper and digital
  - Limit access to information on information system media to authorized users
  - Sanitize or destroy information system media before disposal or release for reuse.
- **Physical and Environmental Protection:**
  - Limit physical access to information systems, equipment, and the respective operating environments to authorized individuals
  - protect the physical plant and support infrastructure for information systems
  - provide supporting utilities for information systems
  - protect information systems against environmental hazards
  - provide appropriate environmental controls in facilities containing information systems.
- **Planning:**
  - Develop, document, periodically update, and implement security plans
  - The security plans describe the security controls in place or planned for the information systems and the rules of behavior for individuals accessing the system.

# Counter-measures (V)

- **Personnel Security:**
  - Ensure that individuals with positions of responsibility (including third-parties) are trustworthy and meet the security criteria for those positions
  - Ensure that organizational information and information systems are protected during and after personnel actions such as terminations and transfers
  - Employ formal sanctions for personnel failing to comply with organizational security policies and procedures.
- **Risk Assessment:**
  - Periodically assess the risk to organizational operations (including mission, functions, image, or reputation), organizational assets, and individuals.
  - Risks may result from the operation of organizational information systems and the associated processing, storage, or transmission of organizational information.
- **Systems and Services Acquisition:**
  - Allocate sufficient resources to adequately protect organizational information systems
  - Employ system development life cycle processes that incorporate information security considerations
  - Employ software usage and installation restrictions
  - Ensure that third-party providers employ adequate security measures to protect information, applications, and/or services outsourced from the organization.

# Counter-measures (VI)

- **System and Communications Protection:**

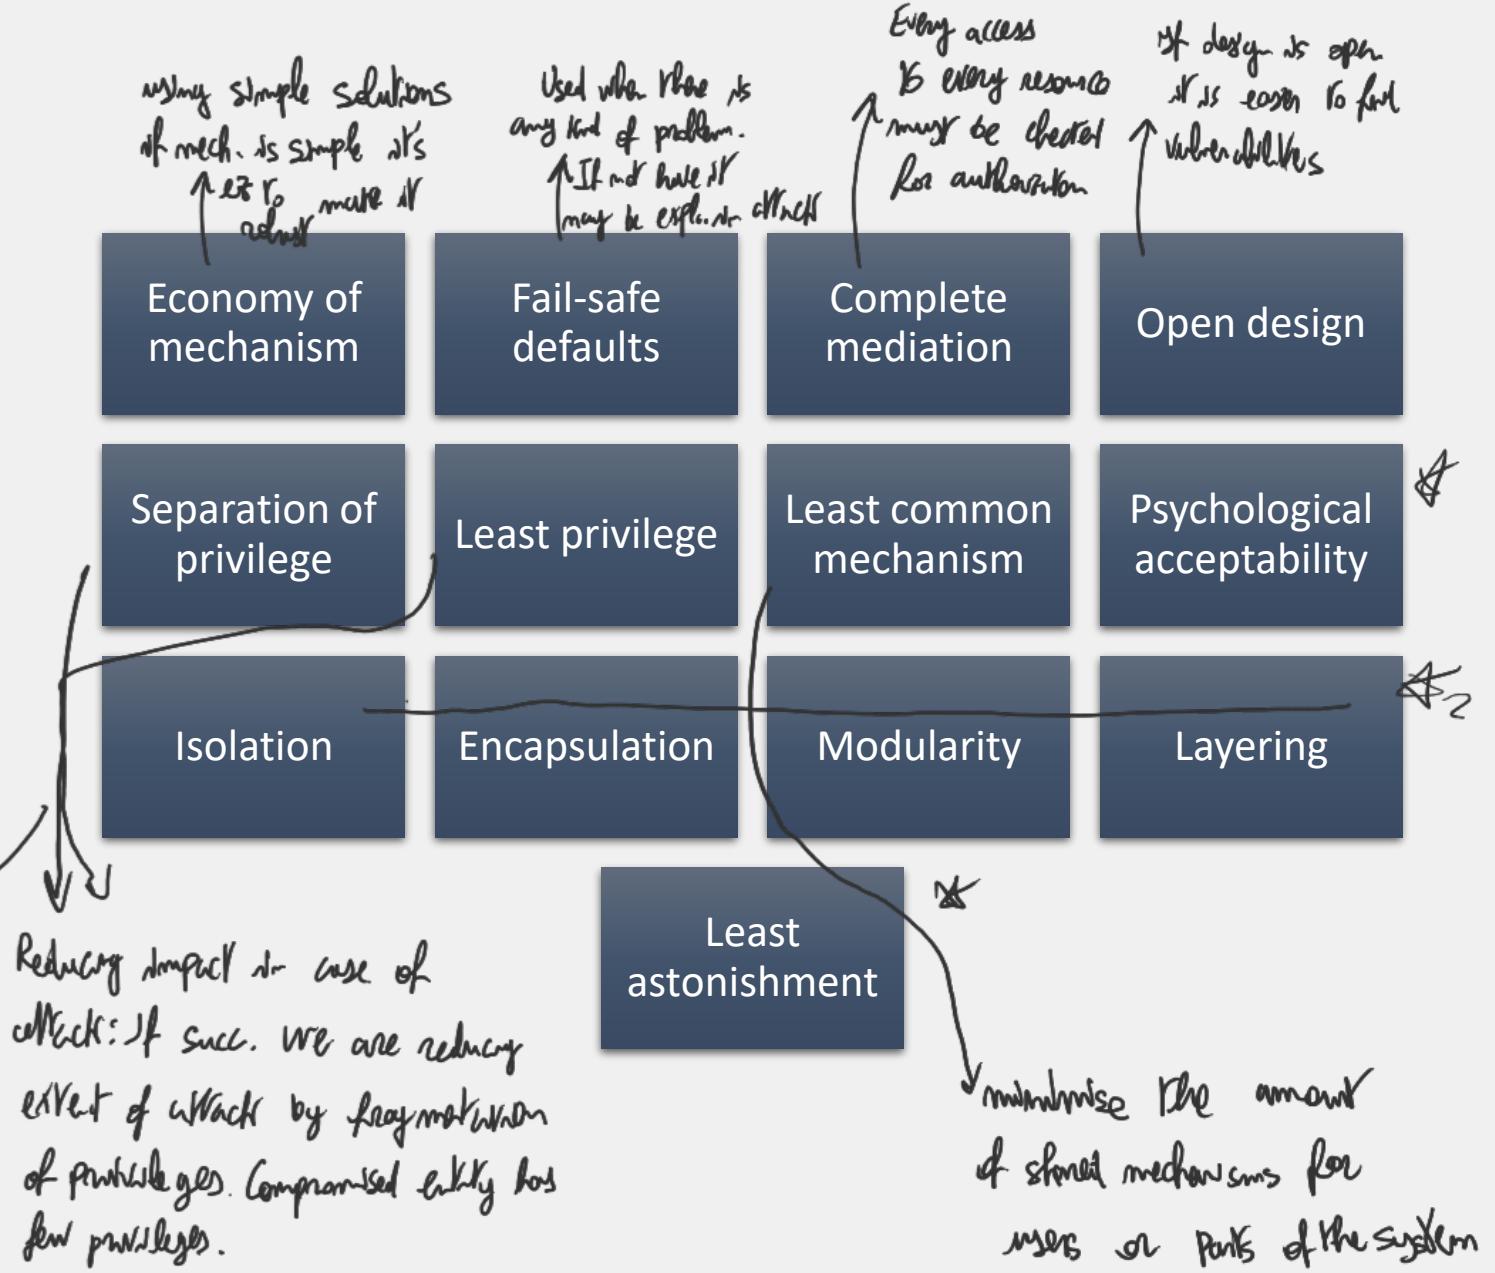

- Monitor, control, and protect organizational communications (both transmitted and received) at the external boundaries and key internal boundaries of the information systems
- Employ architectural designs, software development techniques, and systems engineering principles that promote effective information security within organizational information systems.

- **System and Information Integrity:**

- Identify, report, and correct information and information system flaws in a timely manner
- Provide protection from malicious code at appropriate locations within organizational information systems
- Monitor information system security alerts and advisories and take appropriate actions in response.

# Fundamental Security Design Principles

Give the small amount of privileges required

- (PSYCHOLOGICAL) (LEAST)
- ☒ Design cont. so that they are understood and not confusing so that we do not introduce vulnerabilities.
    - ↓
    - Push a lot for password examples.
  - ☒ Concern the way we design systems. Components operate in isolation and go into direction of least privilege separation of privileges.

## ...Fundamental Security Design Principles...

finally, a quote from Hoare:

"there are two ways of constructing a software design: One way is to make it so simple that there are obviously no deficiencies, and the other way is to make it so complicated that there are no obvious deficiencies."

# Review question

---

WHAT KIND OF COUNTERMEASURES ARE THE FOLLOWING:

- 1) ENCRYPTION OF THE SSD OF A LAPTOP
- 2) KEEPING THE HASH OF EXECUTABLE FILES OF THE OS IN A CD
- 3) UNINSTALLATION FROM THE SYSTEM OF UNUSED APPLICATIONS

# Problem NO FAIL SAFE DEFAULTS; default is else.

---

Consider the following general code for allowing access to a resource:

```
DWORD dwRet = IsAccessAllowed(...);  
if (dwRet == ERROR_ACCESS_DENIED) {  
    // Security check failed.  
    // Inform user that access is denied.  
} else {  
    // Security check OK.  
}
```

- a. Explain the security flaw in this program.
- b. Rewrite the code to avoid the flaw.

# Attack surfaces and security strategies

---

# Attack surfaces

---

Consist of the reachable and exploitable vulnerabilities in a system

Examples:

Open ports on outward facing Web and other servers, and code listening on those ports

Services available on the inside of a firewall

Code that processes incoming data, email, XML, office documents, and industry-specific custom data exchange formats

Interfaces, SQL, and Web forms

An employee with access to sensitive information vulnerable to a social engineering attack

# Attack surface categories

---

REPET.

## Network Attack Surface

Vulnerabilities over an enterprise network, wide-area network, or the Internet

Network protocol vulnerabilities (e.g. those used for DoS attacks);

disruption of communications links;

various forms of intruder attacks

## Software Attack Surface

Vulnerabilities in application, utility, or operating system code

Particular focus is Web server software

## Human Attack Surface

Vulnerabilities created by personnel or outsiders, such as social engineering, human error, and trusted insiders

# Attack surface analysis

---

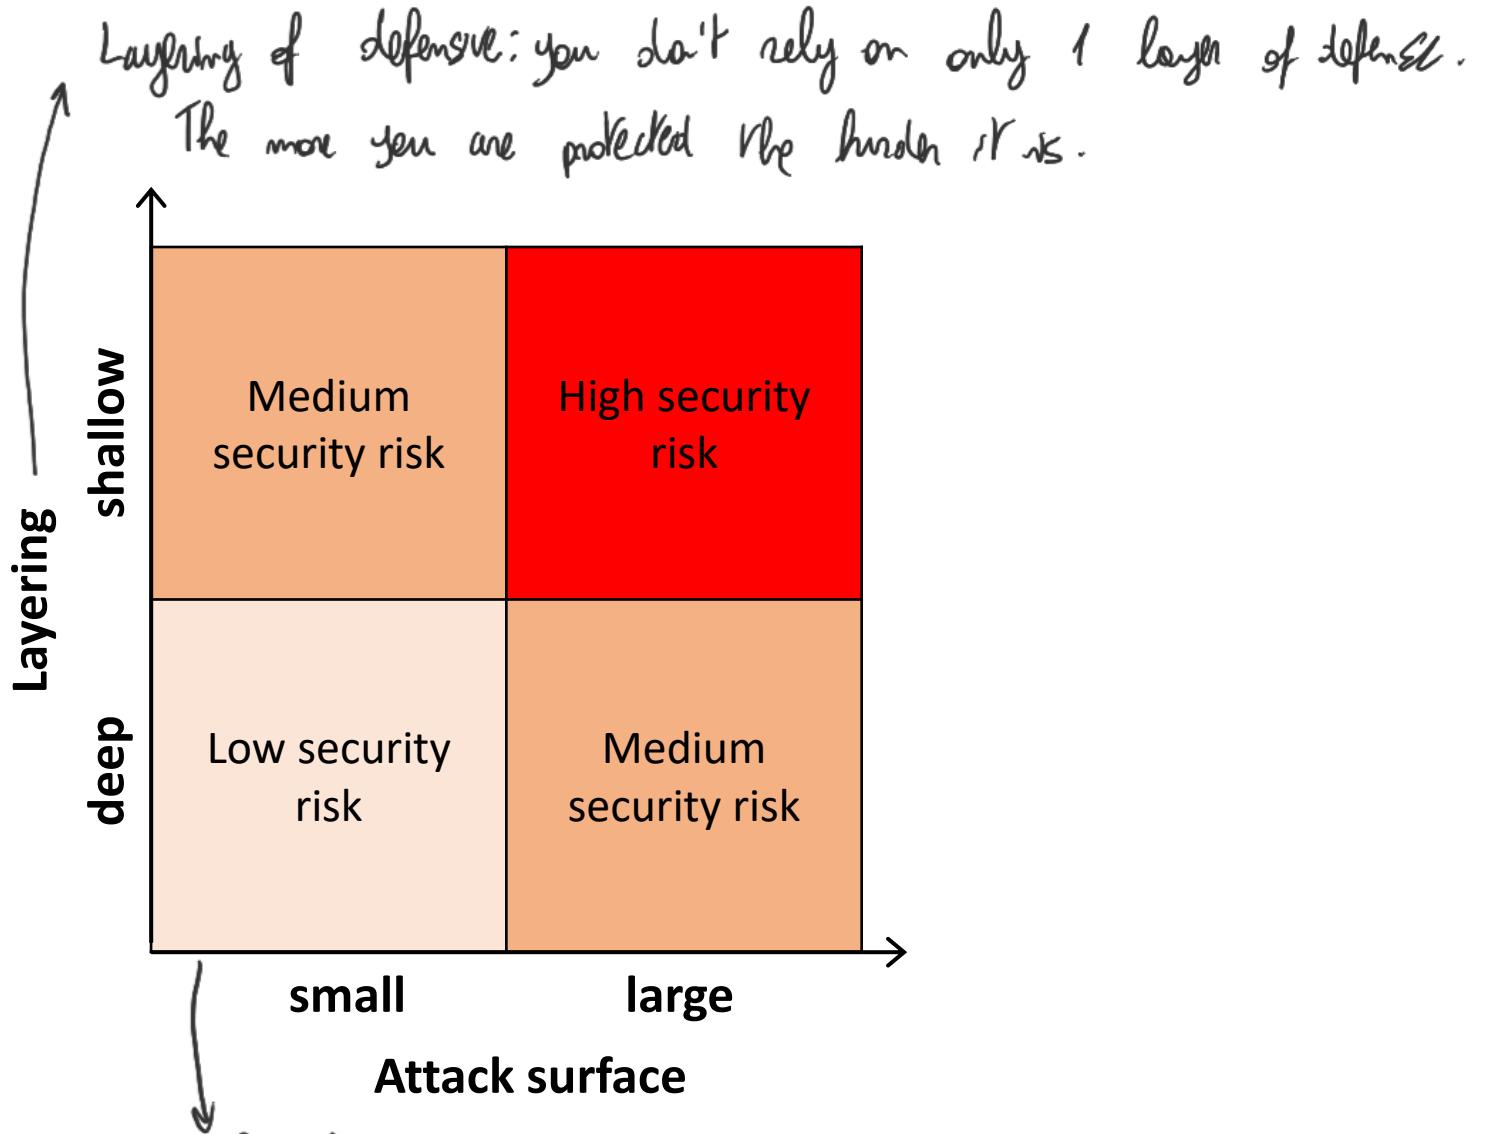

Larger attack surfaces increases the risk

- To assess the scale and severity of threats to a system:
  - Identifies the points of vulnerability (more just vulnerabilities)
  - Identifies the most appropriate security mechanisms and their deployment
- Uses:
  - Makes developers and security analysts aware of where security mechanisms are required.
  - Designers may be able to find ways to make the surface smaller, thus making the task of the adversary more difficult.
  - It also provides guidance on setting priorities for testing, strengthening security measures, or modifying the service or application.

\* Points that could have vulnerabilities.

Attack surface is whenever its accessible by internal or external entities.

# Defense in depth and attack surface

Remember: risks are also dependent on the impact of an attack.

# Attack trees

---

↑  
Way to do analysis

- An attack tree is a branching, hierarchical data structure that represents a set of potential techniques for exploiting security vulnerabilities:
  - The root of the tree is the *security incident* (the goal of the attack)
  - The branches and subnodes of the tree are the ways that an attacker could reach that goal
  - Each subnode defines a subgoal, and each subgoal may have its own set of further subgoals, etc.
  - The leaf nodes, represent different ways to initiate an attack.

# Attack trees

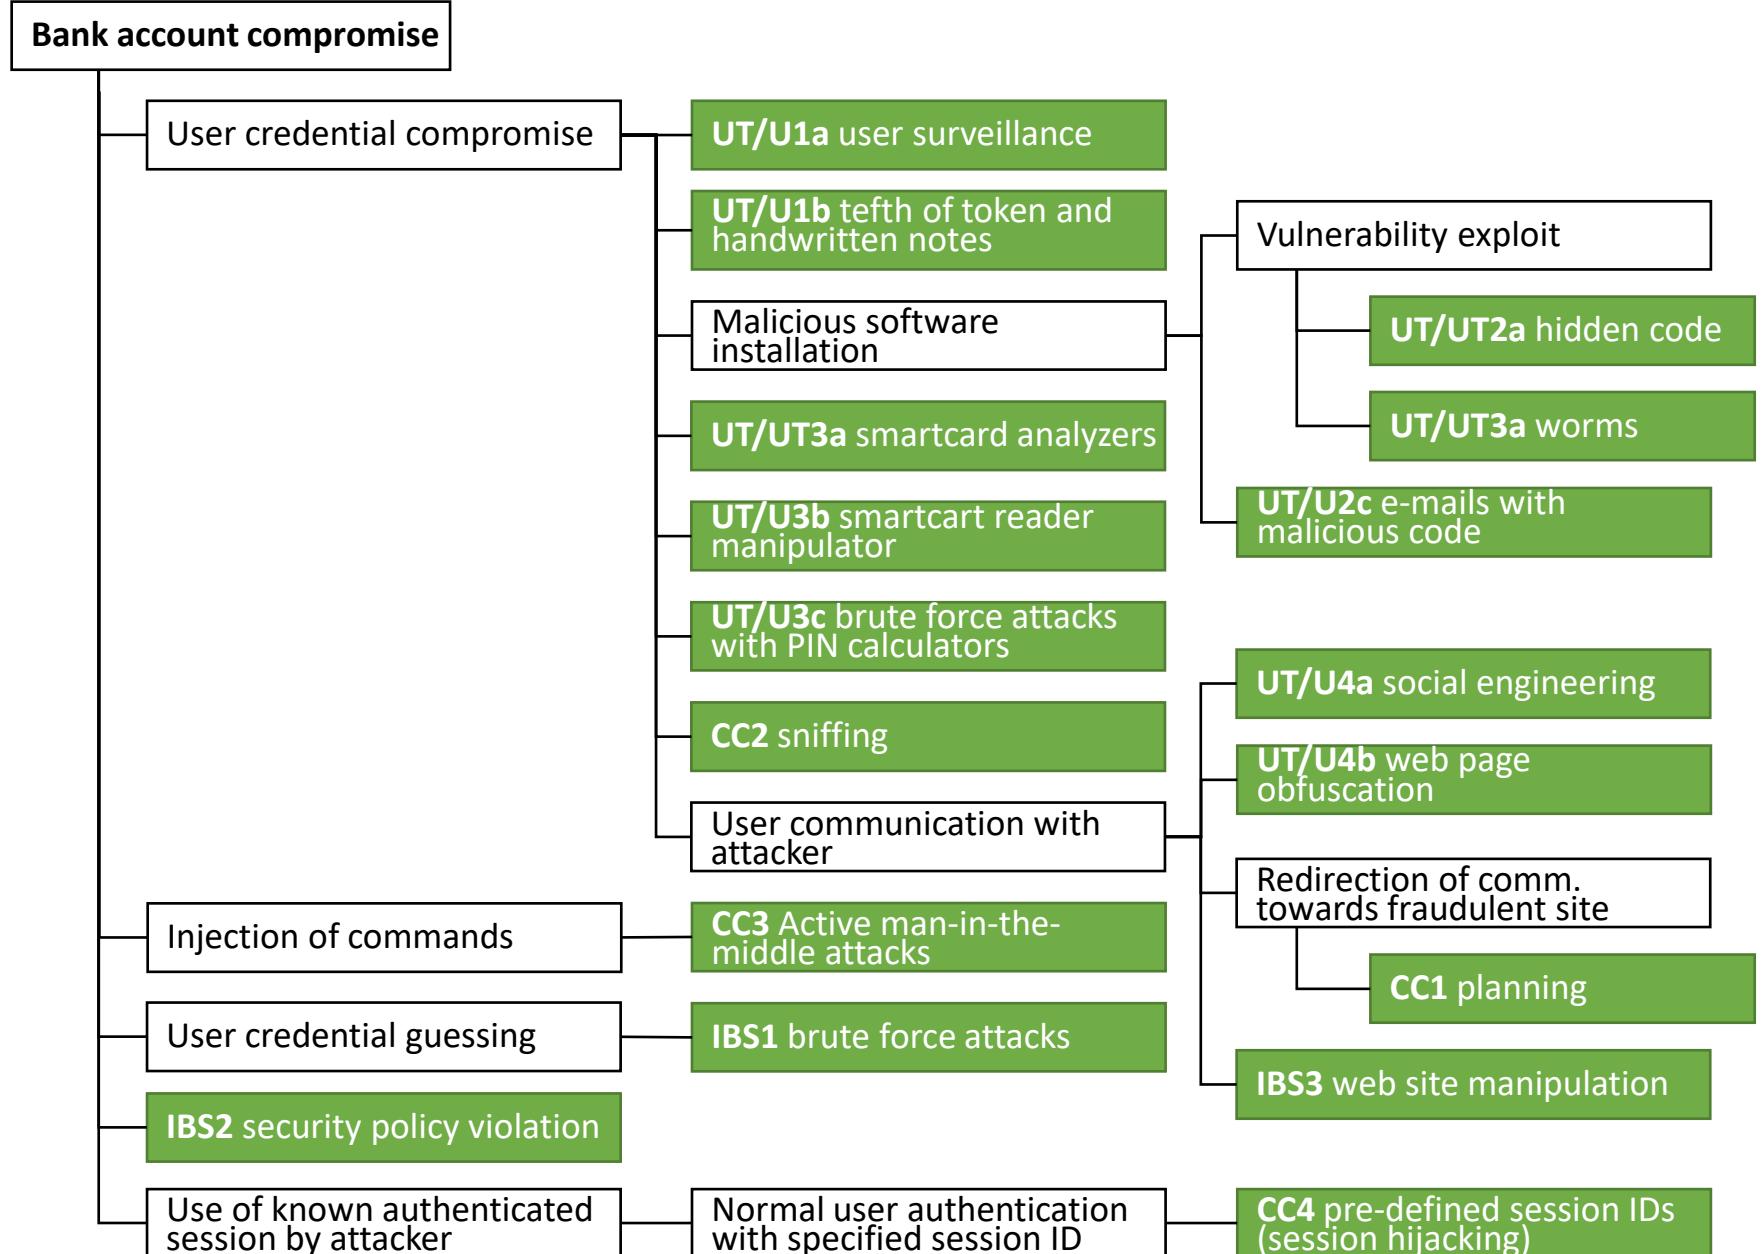

---

- Each node other than a leaf is either an AND-node or an OR-node:
  - To achieve the goal represented by an AND-node, the subgoals represented by all of that node's subnodes must be achieved
  - for an OR-node, at least one of the subgoals must be achieved.
- Branches can be labeled with values representing difficulty, cost, or other attack attributes, so that alternative attacks can be compared.
- Attack trees allow analysis attack patterns:
  - to build a body of knowledge about both attack strategies and patterns.
  - to document security attacks in a structured form that reveals key vulnerabilities.
  - to guide the design of systems and applications, and the choice and strength of countermeasures.

# Attack trees

---

# Computer security strategies

## SUMMARISE

### Security Policy

- Formal statement of rules and practices that specify or regulate how a system or organization provides security services to protect sensitive and critical system resources (RFC 4949)

### Security Implementation

- Involves four complementary courses of action:
  - Prevention
  - Detection
  - Response
  - Recovery

### Assurance

- It is an attribute of an information system that encompasses both system design and implementation
- Provides grounds for having confidence that the system operates such that the system's security policy is enforced

### Evaluation

- Process of examining a computer product or system with respect to certain criteria
- Involves testing and may also involve formal analytic or mathematical techniques

define what

terms of rules, practices what tells how security should be managed and which entity can do what.

Setting up controls

# Computer security strategies

## Security Policy

- Rules and practices
- Specify/regulate how a system or organization provides security services
- Aim at protecting sensitive and critical system resources
- (RFC 4949)

## Security Implementation

- Involves four complementary courses of action:
  - Prevention
  - Detection
  - Response
  - Recovery

## Assurance \*

- A formal proof or an informal one
- Concerning the security property of a design/implementation of a system
- Gives confidence that the security policy of a system are enforced

## Evaluation

- Process of examining a computer product or system with respect to certain criteria
- Involves testing and may also involve formal analytic or mathematical techniques

\* Operate on the design and on the theoretical system.  
On eval you make tests.

# Security policy

---

- Several factors to be considered in the development of a security policy:
  - The value of the assets being protected
  - The vulnerabilities of the system and. the impact of threats on assets.
  - Potential threats and the likelihood of attacks assets.
- Relevant tradeoffs: you do not want to pay for overkill
  - Ease of use versus security
  - Cost of security versus cost of failure and recovery
- The security policy is a business decision, possibly influenced by legal requirements.
  - ↓ implementation vs technical.

# Security implementation

---

**Prevention:** an ideal security scheme is one in which no attack is successful...

- Example: transmission of encrypted data

**Detection:** absolute protection is often not feasible, but it is practical to detect security attacks.

- Example: intrusion detection systems designed to detect the presence of unauthorized individuals logged onto a system.

**Response:** if security mechanisms detect an ongoing attack, the system may be able to respond in such a way as to halt the attack and prevent further damage.

**Recovery:** an example of recovery is the use of backup systems, so that if data integrity is compromised, a prior, correct copy of the data can be reloaded.

# Assurance and evaluation

---

**Assurance** is an attribute of a system that provides confidence that the system operates such that the system's security policy is enforced.

- Encompasses both system design and implementation.
- Deals with the questions:
  - “Does the security system design meet its requirements?”
  - “Does the security system implementation meet its specifications?”
- It is expressed as a degree of confidence, not in terms of a formal proof that a design or implementation is correct.
  - Absolute proofs not possible at the state of the art

**Evaluation** is the process of examining a computer product or system with respect to certain criteria.

- involves testing, formal analytic or mathematical techniques.

# Conclusions

---

- Standards have been developed to cover management practices and the overall architecture of security mechanisms and services
- The most important of these organizations are:
  - National Institute of Standards and Technology (NIST)
    - NIST is a U.S. federal agency that deals with measurement science, standards, and technology related to U.S. government use and to the promotion of U.S. private sector innovation
  - Internet Society (ISOC)
    - ISOC is a professional membership society that provides leadership in addressing issues that confront the future of the Internet, and is the organization home for the groups responsible for Internet infrastructure standards
  - International Telecommunication Union (ITU-T)
    - ITU is a United Nations agency in which governments and the private sector coordinate global telecom networks and services
  - International Organization for Standardization (ISO)
    - ISO is a nongovernmental organization whose work results in international agreements that are published as International Standards

# Standards
